Task description

You are given two non-empty arrays A and B consisting of N integers. Arrays A and B represent N voracious fish in a river, ordered downstream along the flow of the river.

The fish are numbered from 0 to N − 1. If P and Q are two fish and P < Q, then fish P is initially upstream of fish Q. Initially, each fish has a unique position.

Fish number P is represented by A[P] and B[P]. Array A contains the sizes of the fish. All its elements are unique. Array B contains the directions of the fish. It contains only 0s and/or 1s, where:

- 0 represents a fish flowing upstream,
- 1 represents a fish flowing downstream.

If two fish move in opposite directions and there are no other (living) fish between them, they will eventually meet each other. Then only one fish can stay alive − the larger fish eats the smaller one. More precisely, we say that two fish P and Q meet each other when P < Q, B[P] = 1 and B[Q] = 0, and there are no living fish between them. After they meet:

- If A[P] > A[Q] then P eats Q, and P will still be flowing downstream,
- If A[Q] > A[P] then Q eats P, and Q will still be flowing upstream.

We assume that all the fish are flowing at the same speed. That is, fish moving in the same direction never meet. The goal is to calculate the number of fish that will stay alive.

For example, consider arrays A and B such that:

Solution

Programming language used:	Swift 4
Total time used:	4 minutes
Effective time used:	4 minutes

Task timeline

10:02:59 10:06:41

Code: 10:06:41 UTC, swift4, final, score: **100** show code in pop-up

```
1  import Foundation
2  import Glibc
3
4  public struct Stack<T> {
5      fileprivate var array = [T]()
6
7      public var isEmpty: Bool {
8          return array.isEmpty
```

```
A[0] = 4    B[0] = 0
A[1] = 3    B[1] = 1
A[2] = 2    B[2] = 0
A[3] = 1    B[3] = 0
A[4] = 5    B[4] = 0
```

Initially all the fish are alive and all except fish number 1 are moving upstream. Fish number 1 meets fish number 2 and eats it, then it meets fish number 3 and eats it too. Finally, it meets fish number 4 and is eaten by it. The remaining two fish, number 0 and 4, never meet and therefore stay alive.

Write a function:

```
public func solution(_ A : inout [Int], _ B : inout
[Int]) -> Int
```

that, given two non-empty arrays A and B consisting of N integers, returns the number of fish that will stay alive.

For example, given the arrays shown above, the function should return 2, as explained above.

Write an **efficient** algorithm for the following assumptions:

- N is an integer within the range [1..100,000];
- each element of array A is an integer within the range [0..1,000,000,000];
- each element of array B is an integer that can have one of the following values: 0, 1;
- the elements of A are all distinct.

```
9       }
10
11      public var count: Int {
12          return array.count
13      }
14
15      public mutating func push(_ element: T) {
16          array.append(element)
17      }
18
19      public mutating func pop() -> T? {
20          return array.popLast()
21      }
22
23      public var top: T? {
24          return array.last
25      }
26  }
27
28  extension Stack: Sequence {
29      public func makeIterator() -> AnyIterator<T> {
30          var curr = self
31          return AnyIterator {
32              return curr.pop()
33          }
34      }
35  }
36
37  public func solution(_ A : inout [Int], _ B : inout [I
38
39      var stack = Stack<Int>()
40      let N = A.count
41      var live = N
42
43      for i in 0...N-1 {
44          if B[i] == 0 {
45              inner: while let top = stack.top {
46                  if A[top] < A[i]{
47                      stack.pop()
48                      live -= 1
49                  }else{
50                      live -= 1
51                      break inner
52                  }
53              }
54          }else{
55              stack.push(i)
56          }
57      }
58
59      return live
60  }
```

Analysis summary

The solution obtained perfect score.
